

Remote home supervision and control

Abstract:

This little board allows you to remotely manage your summer cottage. Maybe you plan to go to your cottage in early spring or late fall and it is already a bit cold. Instead of "freezing" the first day you can now remotely turn on the heating a day earlier using your web browser.

You can always see what the indoor and outdoor temperatures are and how humid it is inside. This saves you also a lot of energy cost because you do not have to keep the heating all the time on while you are away.

What we use

This project combines the SHT11 temperature and humidity sensor together with the ds18s20 temperature sensor.

The SHT11 is ideal for indoor use. It requires a short cable length between ethernet board and sensor. It can measure temperature and humidity. Both are very important factors to maintain a comfortable and healthy climate. Nobody wants mold in the building.

ds18s20 is a very good outdoor sensor. You can have a long cable (about 10m, 33foot) between sensor and ethernet board and the sensor is fairly robust with regards to water exposure. You should keep it dry but it will survive it case it gets accidentally rained on.

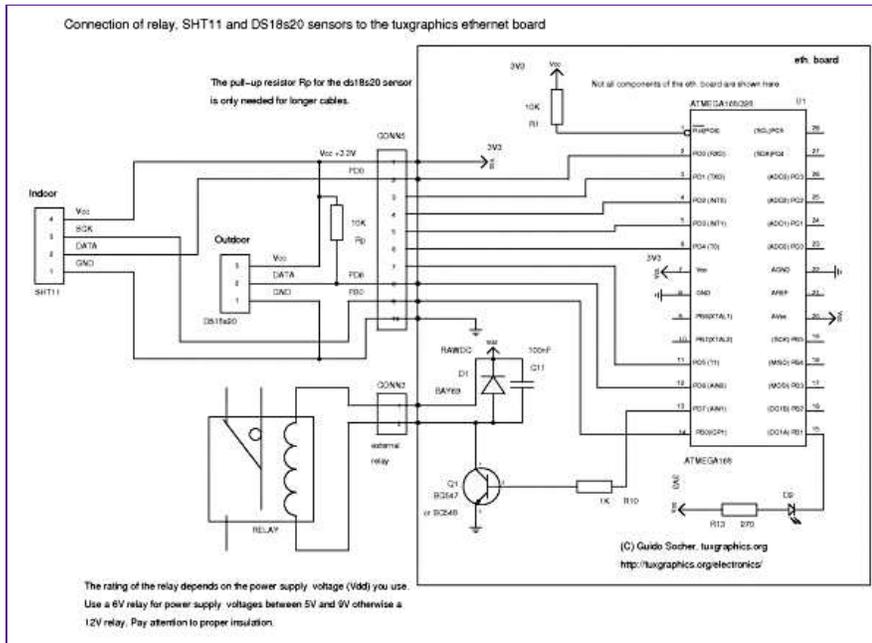

There is also a new feature: the possibility to export long term measurement data into a column separated values file (CSV file) for import into a spreadsheet.

What is the dew point?

The ds18s20 is a pure temperature sensor. The SHT11 is a combined temperature and humidity sensor. The SHT11 makes it possible to accurately calculate the dew-point. The dew-point temperature is the temperature to which the air must be cooled to reach saturation. When the temperature cools to the dew point, fog or dew can occur.

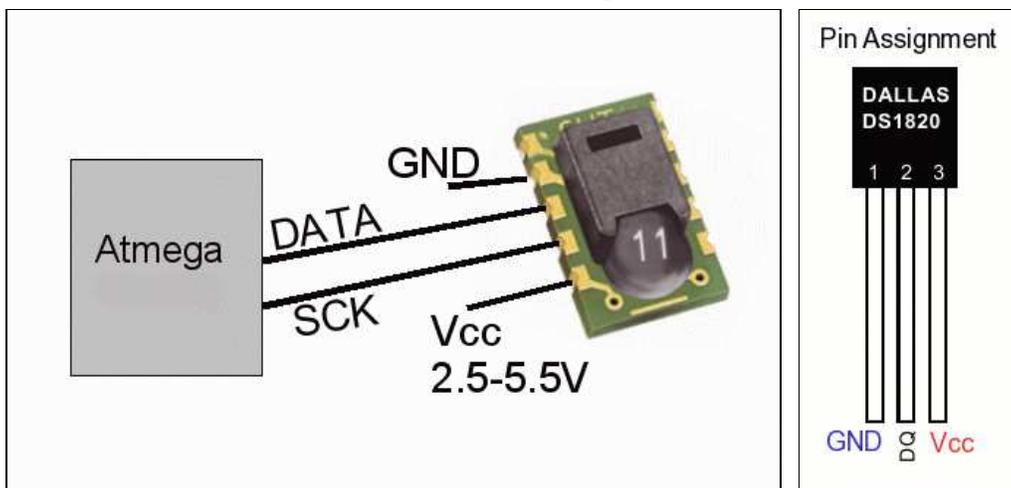

Example: In your bath room you measure 23°C and 61% humidity. The resulting dew point is about 15°C. If your window or wall temperature would be 15°C or less then it would become wet.

Connecting the sensors

Click on the circuit diagram to open it as PDF file

The above circuit diagram shows how to connect the sensors to the microcontroller on the ethernet board. The two sensors are fully digital and already calibrated. A pull-up resistor is required for the outdoor sensor if the cables length is above 2m (6foot). The resistor can be soldered onto the dotmatrix field of the ethernet board. The pin-out of the two sensors is as follows.

The circuit allows also for the connection of a relay which can then be used to switch something remotely on or off (e.g the heating).

Cable length

This solution gives you a lot of flexibility. Ethernet cables can be very long (100m, 330ft). The board can therefore be located almost anywhere in the house. There should be a short cable between SHT11 indoor sensor and ethernet board (50cm, 1.6ft). A long cable can be used between the ds18s20 outdoor sensor and the ethernet board. A cable of 10m (33ft) has been used successfully for the outdoor sensor. A 10K pull-up resistor as shown in the above circuit diagram is recommended for an outdoor sensor cable length over 2m (6ft).

Connecting to the internet

The ethernet board provides a web server with the possibility to control the relay and read the sensors. To access it remotely over the internet you will need a DSL router with port forwarding. Most DSL routers can do that.

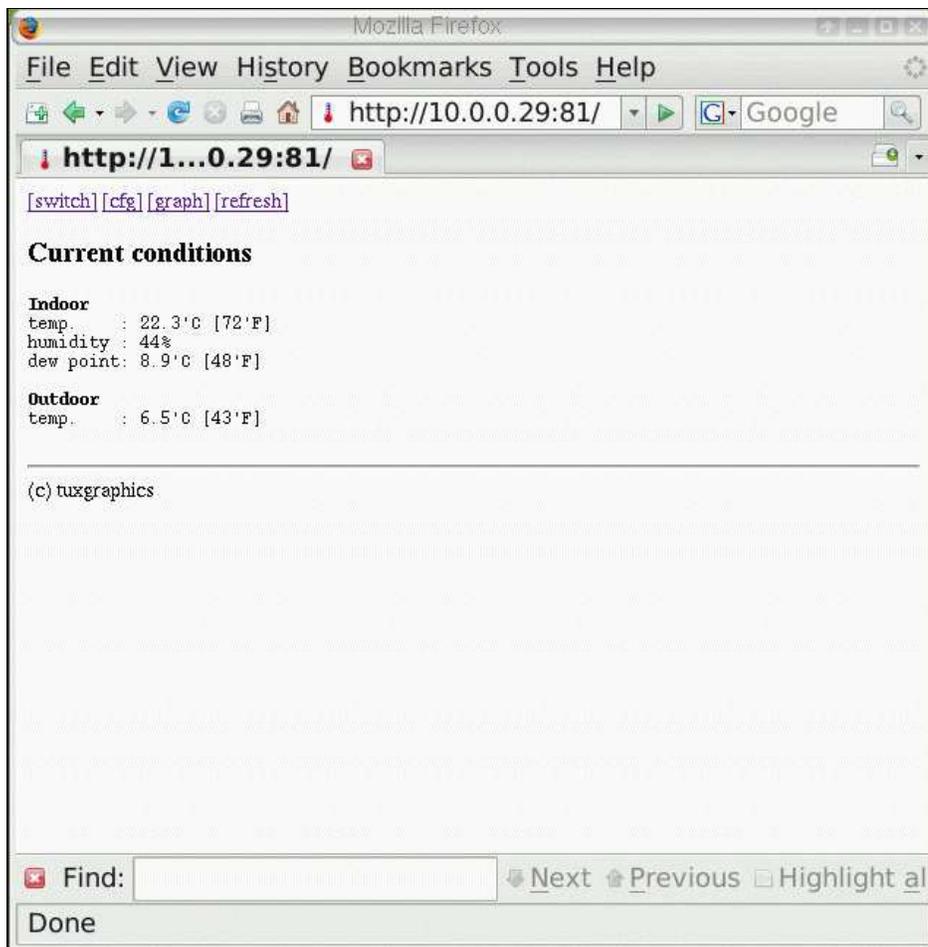

To know where your system is you will either need a static IP address or a DSL router that can work with dyndns.org. The best and most reliable solution is to use a static IP address. Many smaller internet service providers offer static IP addresses for a small additional fee. With tuxgraphics.org/cgi-bin/checkip you can see what your current IP address is. You can use this during initial testing while you do not yet have a static IP or a dyndns.org account.

You can have more than one of those boards connected to one DSL router. All you need to do is use different port numbers.

	Internal IP address and port	External URL
board 1:	192.168.0.4 port 80	http://my.summer.house/
board 2:	192.168.0.5 port 81	http://my.summer.house:81/

The web pages

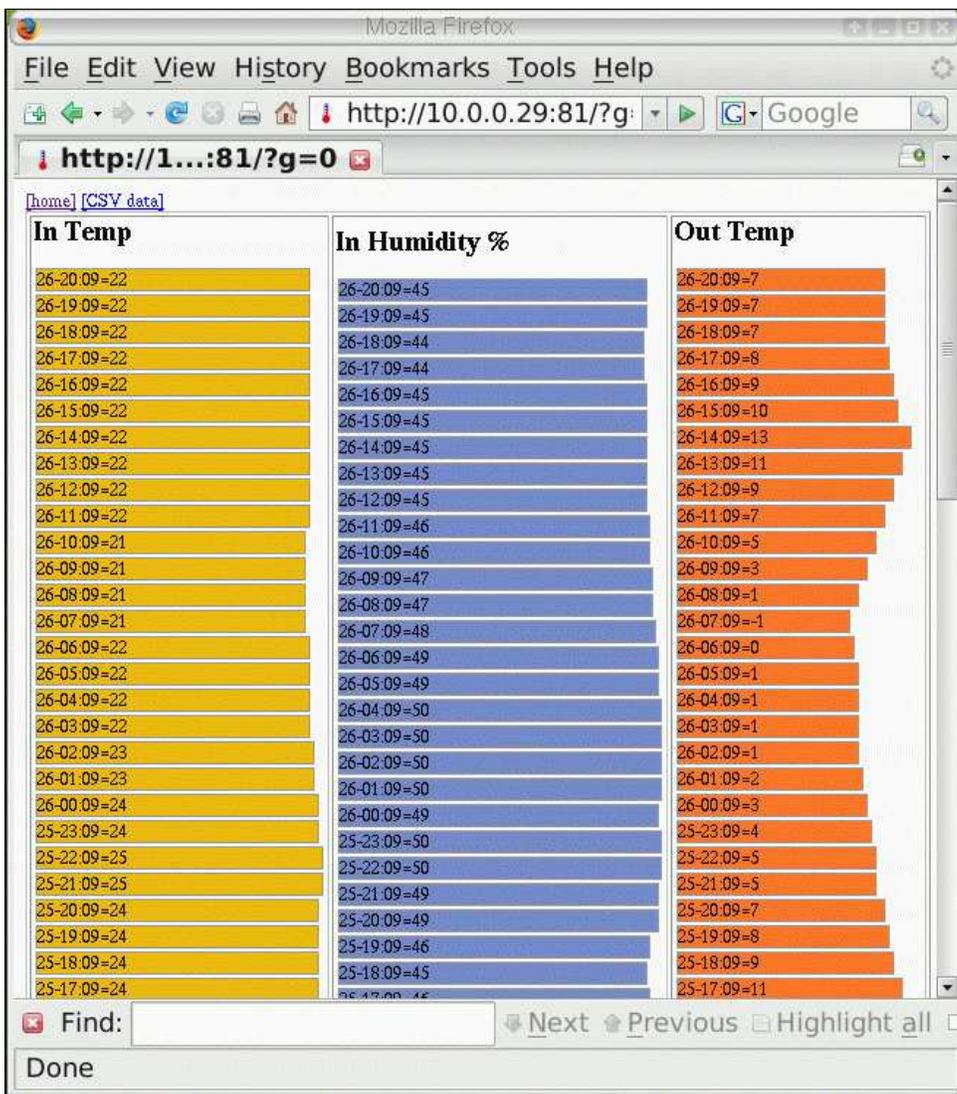

Here is what this solution looks like. The main window shows the current situation. On top is the menu to get to the other pages.

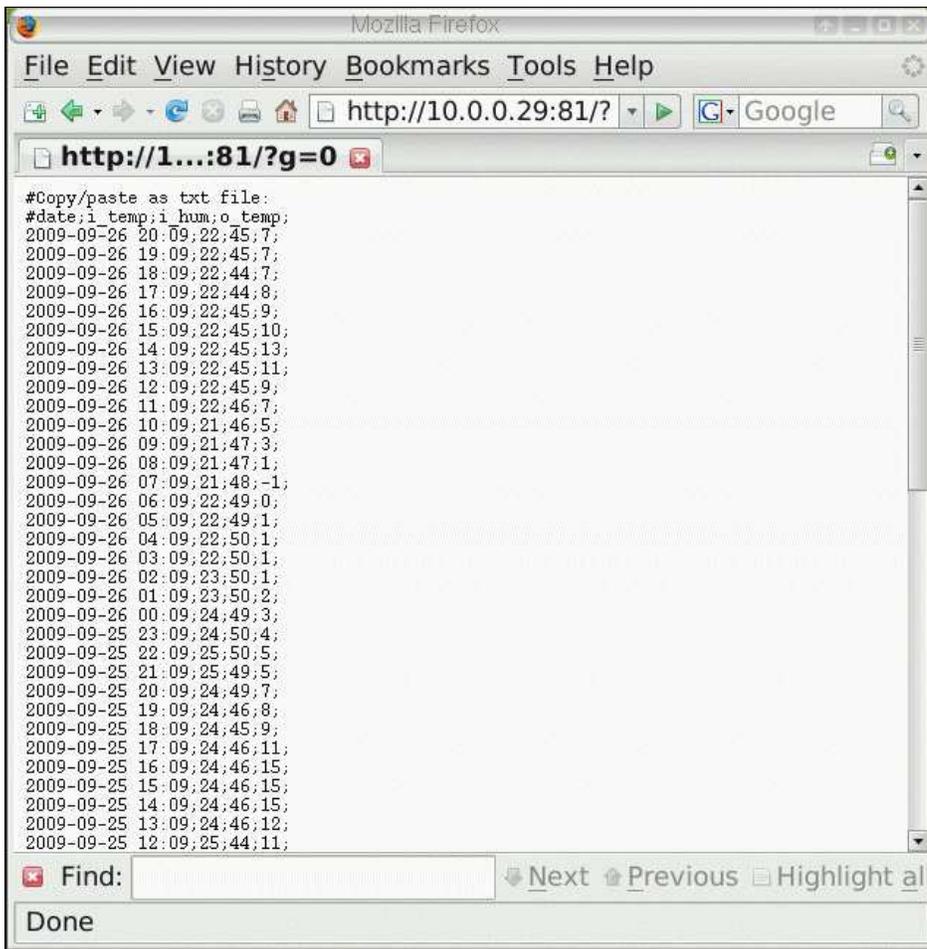

The relay control page allows you to switch on or off something using your password.

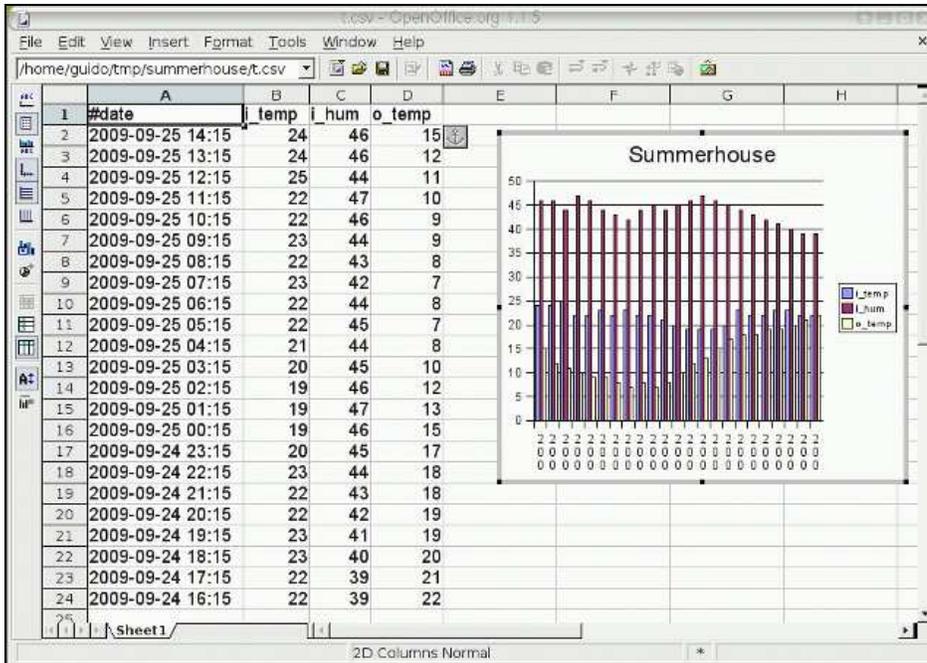

Clicking on "graph" takes you to a page where you can see historic data plotted as a bar-graph.

Clicking on "CSV data" you can get the historic data in column separated values format for import into a spreadsheet.

The data imported into a spreadsheet.

There is also a possibility to customize the recording interval. That is: the time periods at which samples are recorded as bar graphs and data for import into a spreadsheet.

As usual all the pages are designed to work as well on basic mobile data phones. This way you have also access when you are on the road.

Not only for a summer cottage

To have the possibility to control things remotely and read temperature + humidity values makes not only sense for a summer cottage. It is nice to have in any home. You don't need to rely on the weather report to see how warm or cold it is. Just take the iphone out of you pocket and you know what the temperature around your house is.
